Record type: Completed
An immunocytochemical technique utilizing an avidin-biotin peroxidase complex was developed to detect viral antigens in various tissues following oral administration of a locally isolated serotype 8 avian adenovirus (AAV) in specific pathogen-free (SPF) chickens. A strong color reaction was obtained with tissues from infected birds that contained a minimal amount of AAV antigens as determined by an indirect enzyme-linked immunosorbent assay. No reaction was detected in sections of tissues obtained from SPF chickens, and the reactivity with infected tissues could be removed by prior absorption of the primary antibody with purified AAV. A group-specific antigen common to the 12 serotypes of AAV was demonstrated by this technique. Because of the high sensitivity and broad-spectrum reactivity, this technique could be useful for studying the pathogenesis and laboratory diagnosis of inclusion body hepatitis caused by several serotypes of AAV.

Record type: Completed
Two infectious components with buoyant densities of 1.40 g/cm3 and 1.45 g/cm3, designated as major (1.40) and minor (1.45) component, were detected by banding avian adeno-associated virus (AAAV) isopycnically in CsCl. In metrizamide, however, infectious AAAV banded only as a single peak at a density of 1.32 g/cm3. Biological as well as physicochemical properties of the two AAAV components recovered from CsCl density gradient were described. Concerning the minor (1.45) component, three experimental findings may suggest that the capsid structure of this AAAV population is altered in comparison with that of the major (1.40) component: (i) the sedimentation pattern characterized by an additional peak containing slower-sedimenting noninfectious material (16 S); (ii) the specific infectivity decreased by the 3.5 fold; (iii) the ready disintegration when exposed to gently denaturing conditions.

The mechanism of adeno-associated virus (AAV) DNA replication was characterized both genetically and biochemically. In this study, we used monoclonal and polyclonal antibodies to examine the AAV p5 (Rep78 and Rep68) and p19 (Rep52 and Rep40) proteins in infected cells. By overexpressing a truncated Rep78 protein in Escherichia coli, we obtained monoclonal antibody anti-78/68, which is specific for the p5 Rep proteins, and monoclonal antibody anti-52/40, which recognized both the p5 and p19 Rep proteins. In single-fluorochrome indirect immunofluorescence labeling experiments, the viral Rep proteins were localized in distinct intranuclear foci. Analysis of AAV proteins by double-fluorochrome indirect immunofluorescence experiments demonstrated that (i) all four AAV Rep proteins occupied the same intranuclear compartments and (ii) the Rep and capsid proteins colocalized in the nuclei of infected cells. These results suggest that replication centers similar to those established by other viruses exist for AAV. These reagents should provide a useful tool for further delineation of the mechanism of AAV replication in vitro.

Record type: Completed
A new type of defective parvovirus, tentatively designated as adeno-associated virus type 5 (AAV-5), is characterized as far as its proteins, its helper dependence, and its seroepidemiology are concerned. The protein analysis of AAV-5 in polyacrylamide gels demonstrated the presence of three structural polypeptides, corresponding to VP 1, VP 2, and VP 3 of other AAV types. The preparation of monoclonal antibodies against AAV-5 permitted the analysis of viral structural antigen expression by using adenovirus type 12 (Ad 12) or several herpes group viruses as helper viruses, respectively. AAV-5-infected cell cultures coinfected with either Ad 12, Herpes simplex virus (HSV), Cytomegalovirus (CMV), or Varicella Zoster virus (VZV) efficiently synthesize AAV-5 specific antigens. Epstein-Barr virus (EBV) and Herpesvirus saimiri, in contrast, provide only a very weak helper activity for AAV 5 antigen expression. The development of a specific ELISA test permitted screening of human sera for antibodies to AAV-5. Forty-five percent of 926 sera from all age groups and approximately 60% of the adult population reveal antibodies to structural components of this virus. The seroepidemiology differs from that reported for other AAV serotypes. Highest average titers against AAV-5 are observed in the age group between 15 and 20 years. Sera from patients with cervical carcinoma revealed average titers of antibodies well below those of age-matched control groups. Attempts to find higher antibody levels against AAV-5 in specific human diseases failed thus far.

Record type: Completed
Primary infection and reinfection with adeno-associated virus type 4 (AAV-4) was reproduced in green monkeys experimentally infected with AAV-4 in mixture with adenovirus. Wide dissemination of the satellite virus in animals was observed. AAV-4 and its antigen were detectable 5 to 23 days after inoculation. In monkeys infected with a mixture of AAV-4 and adenovirus or with one of them the infection was accompanied by a marked fever persisting from the 5th to the 20th day after inoculation. The infected monkeys showed an intensive rise of homologous antibody titer most marked on the 10th-15th day after inoculation with AAV-4. AAV-4 and its antigen were detected in smears from conjunctival and tonsillar mucosa, rectal specimens in the time course of the infectious process, as well as from the trachea, lungs, liver, spleen, intestines and kidneys of the sacrificed monkeys. Besides, AAV-4 antigen was found in cells of the tonsils and blood leukocytes of the sacrificed monkeys. No virus or its antigen were found in the brain and heart tissues. Virions of adeno-associated virus were found by electron microscopic examinations of kidney cells of one of 3 monkeys infected with AAV-4.

Record type: Completed
The ecologic aspects of the distribution of adeno-associated satellite virus (ASV) in the human population are of great interest because of its unconditional defectiveness and dependence on adenovirus for full and herpesvirus for partial complementation. Adenoviruses and herpesviruses are extremely common and persistent infections in man. We have developed immunofluorescent procedures for detecting the presence of satellite virus antibodies in human sera. The percentage of sera with antibodies to the ASV 2-3 complex was significantly higher in the normal group than in the cancer patients whereas there were no significant differences in herpes antibodies between the groups. The low incidence of satellite antibodies was particularly striking in patients with genital malignancies. The role of ASV's in human disease is not known. Their role in possible abrogation of oncogenesis mediated through adenoviruses or herpesviruses is worthy of further investigation.

Infection with adeno-associated viruses (AAV) early in life and extensive dissemination of these viruses in infants were discovered by detection of AAV antigen by the fluorescent antibody procedure in autopsy materials from infants dying of acute respiratory viral diseases. AAV antigens were found in cells from various organs of infants aged 2,5, 7, 9 days and older. In each individual case AAV of the same serological type was found in different organs. In 4-months-old twins AAV antigens of the same serotypes, 1 and 4, were found in the trachea, lungs, liver, kidney, brains. Out of 21 infants dying of adenovirus infection, 20 had AAV antigens the distribution of which in cells of various organs was analogous to that of the adenovirus antigen, with a few exceptions. Three infants had no adenovirus infection and no AAV antigne. In the other 6 infants no adenovirus antigen but AAV antigens were found. In the latter cases herpes virus infection is not excluded. Possible modes of transmission of AAV infection are discussed.

Record type: Completed
The temperature-sensitive mutant ts4 of adenovirus type 2 (Ad-2) is capable of complementing adeno-associated virus type 1 (AAV-1) in HEp2, KB and HEK cells at 34 degrees C and 39 degrees C when used as a helper virus. Heavy non-infectious AAV-1 particles can be generated by using the mutant ts4 in HEp2 cells. When AAV-1 is grown in serial passages in HEp2 cells, both the wild-type Ad-2 and the mutant ts4 give rise to heavy, less infectious AAV-1 particles. The heavy AAV-1 particles generated by Ad-2 in advanced serial passages retain the property of having CF and IF antigens, but the AAV-1 generated by the mutant in advanced serial passages lose this property. There is no appreciable difference in the particle counts made by electron microscopy of AAV-1 preparations generated either by Ad-2 or the mutant ts4. Analysis by polyacrylamide gel electrophoresis of purified heavy AAV generated by ts4 indicates that in late passage an additional polypeptide of higher mol. wt. than the three structural polypeptides is detected.

A method for preparation of adeno-associated type 4 virus (AAV-4) purified from group-specific adenovirus antigen by adsorption on formalinized sheep erythrocytes and elution into hypertonic NaCl solution was developed. In 1 M naCl solution the purified AAV-4 retained its infectivity and the complement-fixing and hemagglutinating activities. Separation of AAV-4 and adenovirus group-specific complement-fixing antigen was based on differences in conditions of their adsorption and elution. AAV-4 was inactivated by treatment with both formalin and hydrogen peroxide but retained its complement-fixing antigen and hemagglutinating properties. The purified antigen or virus is recommended for serologic tests and other purposes.

In hybridization experiments, B19 shows some reactivity with autonomous rodent parvoviruses but none with adenoassociated virus sequences; its termini are more closely related to adenoassociated virus than to autonomous parvoviruses. B19 shares with all parvoviruses regions of conserved homology in the left side of the genome. The absence of an internal promoter and its unusual pattern of transcription sets B19 apart from both dependent and autonomous parvoviruses. Although clearly an autonomous parvovirus, in its extraordinary fastidious behavior B19

resembles a dependent parvovirus, capable of replication only in the special nuclear milieu of terminally differentiating erythroid cells. Adaptations at the molecular level may have been necessary for B19 parvovirus to acquire its high degree of specificity and low level of pathogenicity and thus succeed in human populations. Adeno-associated virus type 1 (AAV-1) interfered with the replication of its murine adenovirus (MAV) helper in primary mouse kidney cells and in 1-day-old ICR mice. Mice carrying AAV-1 acquired via the transplacental route were protected against lethal infection with MAV. The replication of AAV-1 in these mice could be triggered by multiple challenges with MAV, and antibodies to AAV-1 were subsequently detected.
